CATALOGUE OF SEALS FOR ROTATING SHAFTS	24
CATALOGUE OF SEALS FOR SLIDING SHAFTS	41

See current price list for availability of items.
We reserve the right to modify the design and manufacture of the products and materials described in this catalogue.

The pictures of the products are supplied for information only.

The order comprises :

- the contract signed by both parties, or the purchase order and the acknowledgement of receipt,
- eventually, special or specific additional conditions,
- sale general conditions, available upon request are part of the order.

I - GENERAL

I.1 - WHAT IS A SEAL ?

An element forms a sealing function when it prevents the passage of a fluid from one enclosure to another. Such elements are called "Seals".

If the object is to prevent the flow of a fluid from an enclosure into a neighbouring enclosure, **the seal is called a single seal**. If the seal must prevent the flow of another fluid which may be in the second enclosure into the first, **the seal is called a double seal**.

If the two mechanical parts between which the leakage is likely to occur are fixed with relation to each other, **the seal is called a static seal**. If one or both of these parts is moving relative to the other, **the seal is called a dynamic seal**.

In this document, we will only be dealing with **dynamic seals**.

In practice, we only meet two sorts of relative movement, which may or may not be combined :
- linear translation (such as the sliding of a piston in a cylinder),
- rotation (the relative rotation about a common axis of a shaft in a hub or a crank case).

I.2 - TYPES OF SEALS

Many different methods have been or are still used for sealing, such as :

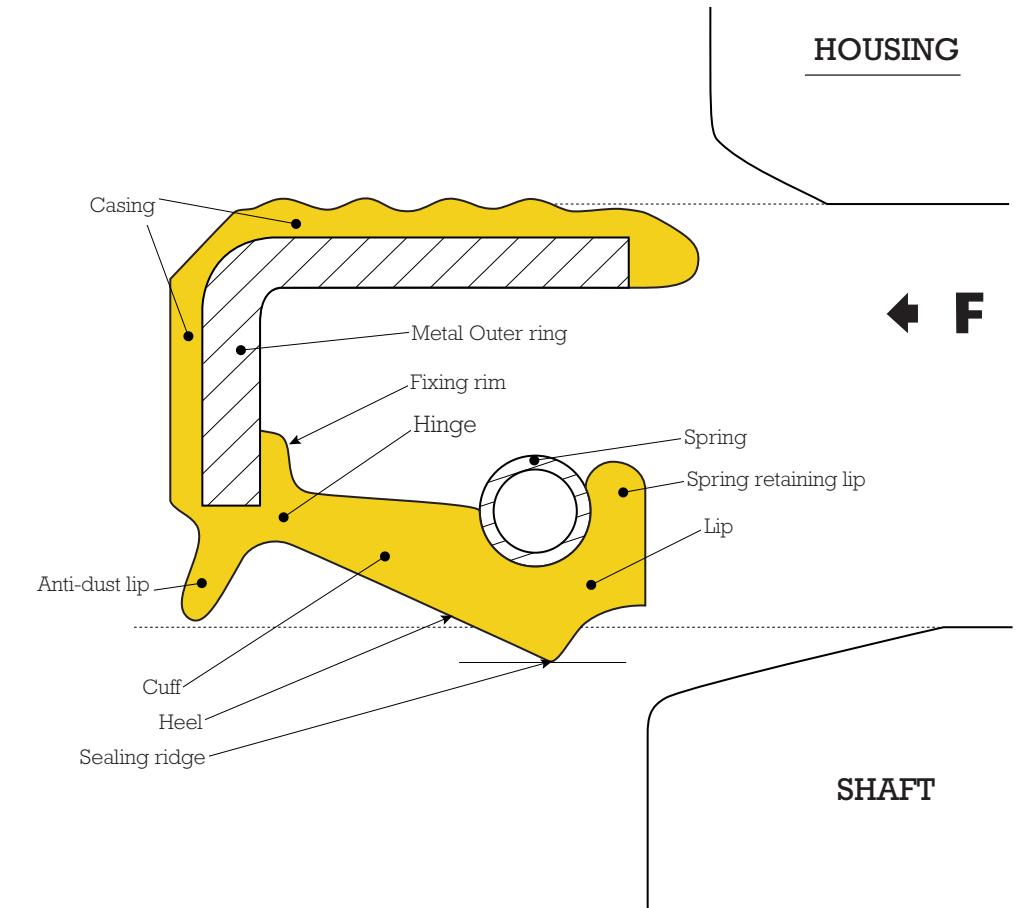

- labyrinth glands,
- stuffing-boxes,
- O-rings,
- lip seals,
- surface seals.

- **Labyrinth glands**, are frictionless seals. They do not provide total sealing and do not seal if completely immersed in the fluid.
- **Stuffing-boxes** work by packing fibrous material which may or may not be braided, tightly around a shaft by means of axial pressure applied by a screw cap or a flange tightened by a bolt, for many years they have been the most common type of seals used. They produce a high frictional torque and absorb a relatively high amount of power. Although for many applications they have been replaced by lip seals or "surface" seals , they are still used a great deal, especially in the case of fluids under high pressure.
- **O-rings** are rings of synthetic elastomer of various cross-sections, most often circular (hence the name), but sometimes in the form of an X or a cross. They are most often used for static seals, but can also be used in some cases as seals for rotating shafts, particularly at low speeds. They also give rise to a high frictional torque.
- **Lip seals for rotating shafts**. Lip seals first appeared about fifty years ago. They consisted of a leather cuff (which could be chromed) whose lip was kept in contact with the rotating shaft by an annular spring. In order to keep both the spring and the leather cuff in position, the parts were encased in a set of metallic collars and rings (normally at least three) which were crimped into each other. The external collar would usually be ground to size and "hard" mounted in a fixed hub. This type of seal was used a great deal, but its life was restricted, as the leather wore out, particularly in high temperatures. Nowadays the leather has been replaced by synthetic elastomers, which appeared on the market some forty years ago and gradually took over the role of the leather. The first of these elastomers to appear is today known as N.B.R. (Nitrile Butadiene Rubber), and was noted for its resistance to organic solvents, in particular liquid fuels and lubricating oils, even at high temperatures. The first seals manufactured had the same structure as the leather seal with its three crimped metal rings. The development of processes which ensure a very good bonding of N.B.R. to metal has enabled the structure of the seal to be simplified and has given it its present classic general shape. The discovery of new elastomers enables us to offer the user an increasingly varied range of seals, which are capable of solving increasingly difficult problems.

Segré's Plant
(Maine-et-Loire)
ISO 9001

I.3 - DESCRIPTION OF LIP SEALS

In outline, a seal for a rotating shaft consists of three essential parts :

- The Outer ring.
- The elastomer.
- The spring.

- **The Outer ring** usually consists of a metal ring in stamped steel with a right-angled cross-section.

- **The elastomer** is itself made up of 3 parts :

- The casing.
- The cuff.
- The lip.

- The casing (from the front surface to the back of the seal) is the part of the elastomer which is bonded to the Outer ring. It can cover it more or less entirely on the interior and/or the exterior.

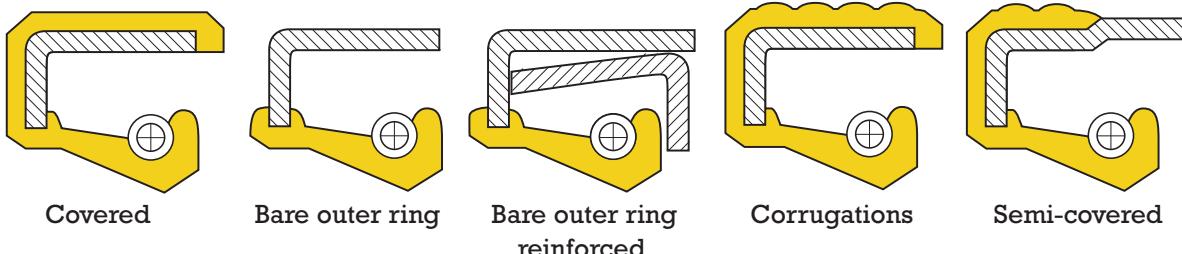

- The cuff is cylindrical or slightly conical in shape, and joins the Outer ring and the casing to the lip. It ensures a static seal, and due to its elasticity - which is greater as it is longer - it allows slight movement of the lip, due to movement of the shaft other than rotation.

- The lip is the element which ensures the dynamic seal by direct frictional contact with the shaft. It is made up of an annular beading including a double bevel forming a sharp ridge which is concentric with the perpendicular axis of the seal. The inclination of the surfaces of the bevel is designed to ensure the seal against leakage of a fluid situated on the side marked **F**.

- **The spring** is a spiral prestressed spring. It forms an annular ring. The join is usually effected by screwing into one end the conical spiral parts of the other end. The spring is fitted by light pressure into a groove in the beading of the lip.

II - SEAL CROSS SECTIONS

II.1 - EXTERNAL SHAPES AND THEIR EVOLUTION

Bare outer ring reinforced

- Good resistance to deformation which is important for large diameters.
- Good resistance to backing out and accurate positioning in the housing.
- Easy assembly for large diameters.
- Protects the seal during pulsating pressures.

Corrugations

- Create a reserve of lubricant and by so doing they make fitting easier.
- Greatly reduce the risk of backing out after fitting.
- An insertion force the same as a smooth shape with a much higher extraction force.

Semi-covered

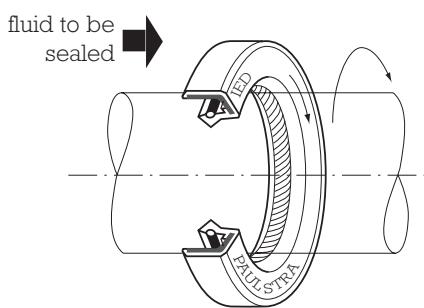

This form combines the qualities of the bare outer ring, that is to say :

- no backing out.
- better positioning.
- higher extraction force.

with that of covered outer ring, which is :

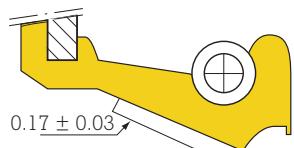

- good static sealing.

II.2 - RIDGED SEALS

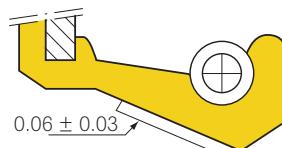

Rear view of the seal :

- Direction of the arrow = direction of rotation of the shaft.
- Ridges to the right (letter D) = clockwise.
- Ridges to the left (letter G) = anticlockwise.
- Bi-directional ridges (letter V).

Truncated ridge

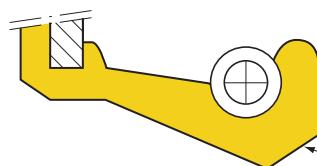

Salient ridge

The efficiency of the ridge increases with its size.

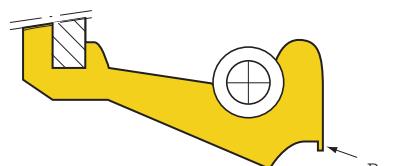

A salient ridge is limited in height by the requirement for continuous contact between the shaft and the lip, which is obtained by the radial load compressing the rubber.

The dimensional limits of a truncated ridge depend essentially on the capability to machine it after moulding. Its manufacture demands much more precision than that of the salient ridge.

II.3 - MOULDED LIP SEALS

Machined lip

Moulded lip

A moulded lip guarantees **a better geometrical fit of the sealing lip** by eliminating the machining tolerances on :

- the lip angle on the fluid side,
- the distance between the edge of the lip and the axis of the spring,
- the length of the lip (i.e. the distance between the fixing rim and the sealing edge).

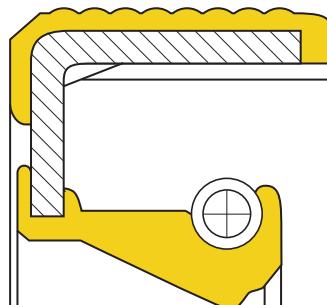

It avoids "**irregularities**" in the sealing ridge which could be caused by the machine tool.

Nowadays, the moulded lip has become a standard technique, thanks to :

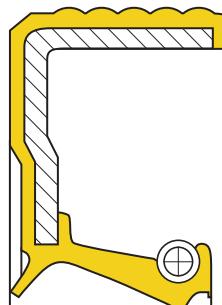

- more accurate machining of the mould,
- suitable means of testing,
- improved vacuum moulding techniques.

II.4 - SEALS WITH MINI-LIPS

Standard seal cross-section

"Paulstra
mini-lip"

The mini-lip has many advantages :

- Reduced dimensions

The decrease in height and the difference between the internal and external diameters allow type IE seals to be used for applications where only type IO used to be possible. The reduced dimensions also mean less weight.

- Less energy loss due to friction

The radial load is smaller, which leads to a decrease of about 30% of the friction torque, which results in :

- a gain in power for the prime mover.
- less heating.

- Increased life

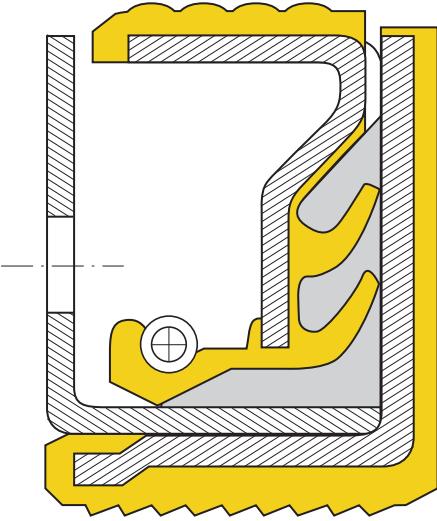

The decrease in heating due to friction results in a lower temperature, which :

- improves the life of the elastomer.
- slow carbonisation, which causes leaks by producing irregularities and stiffening the lip.

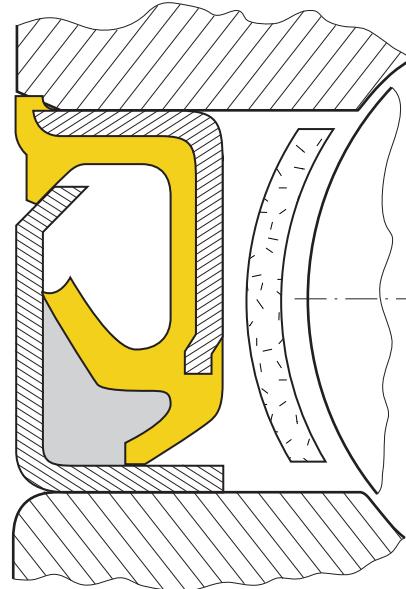

In addition, the reduction of both temperature and carbonisation leads to less wear of the shaft and the seal.

The life of a seal with a mini-lip is thus increased by about 30%.

II.5 - SEALS WITH AN INTEGRATED TRACK

Seal with an
integrated track

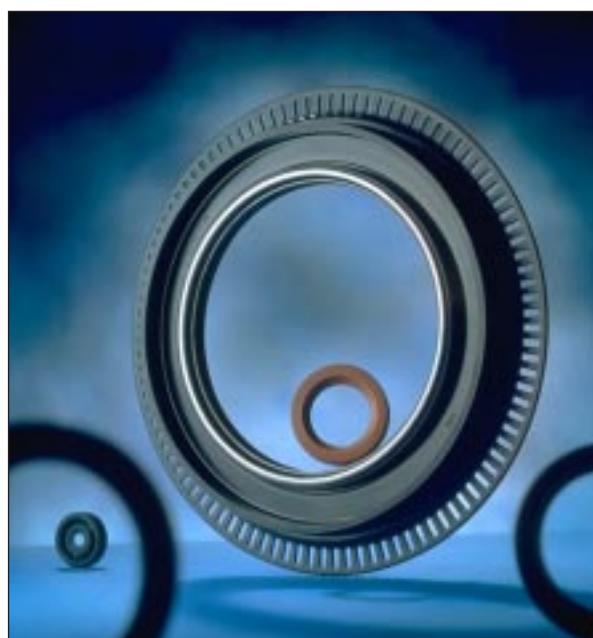

Car wheel seal

This type of seal has its own friction track.

Its main advantages are :

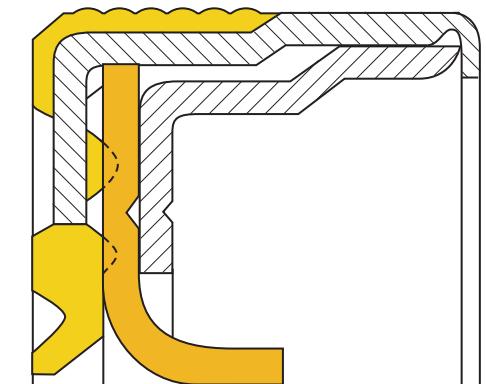

- **reduces the need to grind the shaft,**
- **treatment of only one part,**
- **no shaft wear,**
- **protection of the lip** in storage and handling,
- in a bearing, it can serve as a supporting element until it is fitted in the unit.

The use of this seal is limited by the rotating speed. At present, it is used at up to about 5 m/s.

Integrated track seal
with
Anti-Lock Brakes
detection ring.

II.6 - SEALS WITH TEFLON LIPS

Teflon has the following advantages :

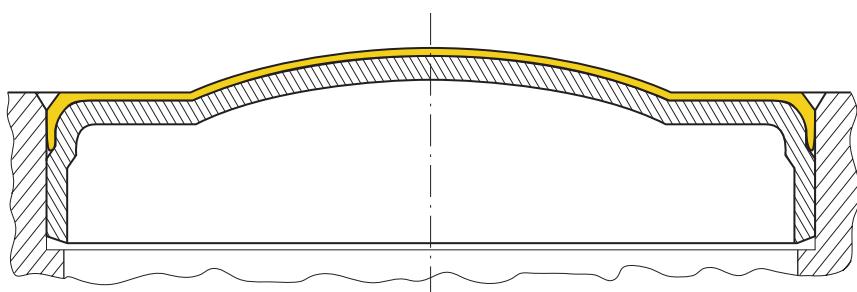

- **a very low coefficient of friction.**
- **resistance to aggressive products.**

The life of this type of seal is much longer than that of elastomer lip seals. As teflon does not have elastomeric properties, the seal is ensured by the hydrodynamic effect of the ridges.

The static seal is ensured by the pressure of the teflon on a beading of elastomer. The use of this type of seal is limited to applications which do not need to be sealed at rest.

II.7 - OTHER PAULSTRA SEALING PRODUCTS

COVERS

In a crankcase, it is sometimes necessary to have temporary access in order to :

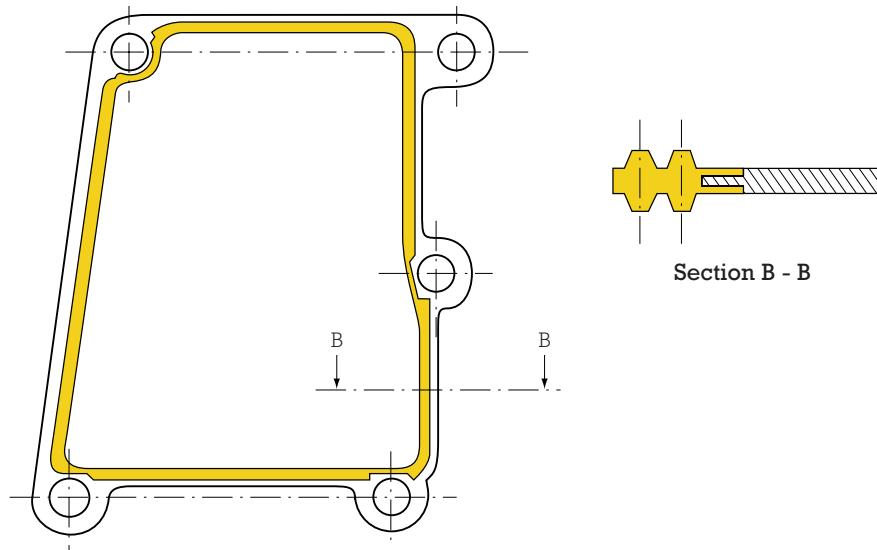

- machine an internal shape which is otherwise inaccessible.
- carry out a mechanical adjustment at the time of assembly.

This type of temporary passage is usually closed by a screwed plate with a flat seal or an O-ring.

Instead of the metal plate, Paulstra offers a rubberised cover which has the following advantages :

- only a simple shape needs to be machined in the crankcase.
- only one part needs to be fitted to ensure the closure of the crankcase with a perfect seal.

FLAT SEALS

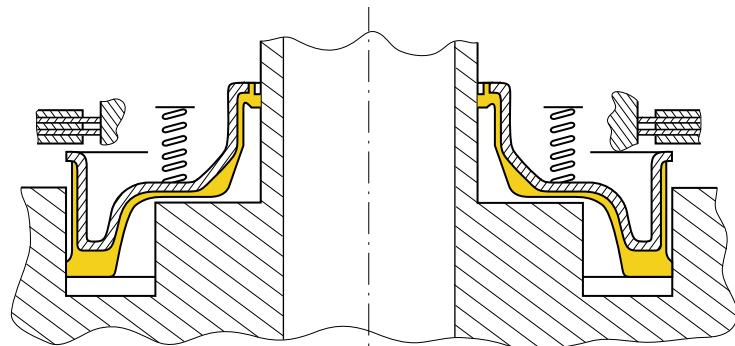

When the fixing screws of a crankcase are being tightened, the reaction of the sealing element (paste or paper) can cause a deformation of the flatness of the seal. This deterioration of flatness often causes leaks when expansion occurs.

To solve this problem, Paulstra offers a metallic-elastomeric seal.

The metal part consists of a thin sheet. The fixing screws which act on this rigid material have no effect on the flatness of the crankcase.

The seal is assured by a beading of elastomer fitted to the inside or the outside of the sheet. The shape of the beading and its attachment to the sheet are designed in such a way that the compression of the elastomer absorbs the faults in the flatness and deformation due to expansion while remaining within acceptable stress constraints.

PISTONS FOR AUTOMATIC GEARBOXES

In an automatic gearbox, the setting in motion and the changing of gears are done by clutches on which pistons, moved by oil pressure, act.

Up to the present, these pistons were in moulded aluminium alloy or steel. The sealing for aluminium pistons was done by elastomer seals of various shapes fitted into the grooves or, for steel pistons, kept in position by outer rings.

Since the seal had to be both interior and exterior, each piston was made up of from 3 to 5 parts, which meant high stocks along with fitting problems, quite apart from being of mediocre efficiency under pressures of 10 to 20 bars.

The type of piston produced by PAULSTRA consists of only one piece of stamped steel onto which are bonded 2 sealing lips. The shape of these lips is adapted to ensure a good seal with little friction and to avoid extrusion.

III - MATERIALS USED

III.1 - ARMATURE

Standard material : sheet steel of XE quality (AFNOR standard A 36 401)
Special outer rings can be produced using other materials for special applications.

III.2 - SPRING

Standard : Stabilised XC 70 steel
On request: Z10 CN 18-09 stainless steel (AFNOR standard A 35 586).

NOTA : All the PAULSTRA range of fluorinated elastomer seals fluorocarbon (FKM) are equipped with stainless steel springs.

III.3 - ELASTOMER

STANDARD MIXES	Mixes	Symbols	Temperature range*
	NITRILE (acrylo-nitrile butadiene) This material is particularly resistant to the action of mineral oils and grease. Suitable in most other cases.	NBR	- 30°C to + 110°C

OTHERS MIXES	Mixes	Symbols	Temperature range*
	POLYACRYLATE Polyacrylate based elastomers have a good temperature resistance, even in the presence of EP oils.	ACM	- 20°C to + 170°C

* Temperatures on samples

Other mixes can be used on request :

• Styrene - butadiene (SBR)

- Ethylene - propylene (EPDM)
- Ethylene - acrylique (EA) (for example Vamac)
- Nitrile hydrogène (HNBR) (for example Therban)

IV - THE SELECTION OF A SEAL FOR A ROTATING SHAFT*

IV.1 - THE TYPE OF FLUID TO BE SEALED

The fluids in contact with each face of the seal can be gases or liquids which are more or less viscous, even pasty (in the case of greases). They must not have too aggressive an action on the materials which make up the seal (the outer ring, spring and elastomer).

IV.1.1 - ARMATURE AND SPRING

The armature and spring of standard seals are steel, so they have a good resistance to all the chemical solvents which are currently used in industry, with the exception of water and aqueous liquids which can cause rust and corrosion.

For any other kind of material, please consult our Technical Services.

IV.1.2 - ELASTOMER

Chemical resistance

The standard seals made from a nitrile elastomer based mix have been designed to resist most current lubricating oils.

For more aggressive fluids, a formula based on fluorinated elastomer fluorocarbon (FKM) would be more appropriate.

FLUIDS	ELASTOMERS				FLUIDS	ELASTOMERS

A: Good chemical resistance

B: Average performance

C: Acceptable (depending on conditions of use)

D: Unsuitable

* For rotating housing applications consult us.

Mechanical resistance

The new brown colored fluorocarbon (FKM) formula presents a very low abrasivity and :

- low shaft and lip wear ;
- resistance to ageing.

Heat resistance

For good performance an elastomeric seal must be used within its operating temperature range. The standard elastomeric mix is not only sensitive to high temperatures which harden it, causing cracks and fissures, but also to intense cold which makes it hard and hardens it. The temperature which must be considered is that at the contact lip. It must be borne in mind that this gets much hotter than the ambient fluid, due to friction. For example, the temperature of the lip of a seal which seals the motor oil of a crankcase, where the shaft is rotating at high velocity (more than 8 m/s), can increase by about fifty degrees after a few minutes of service, whereas the oil, even next to the seal, will only warm up by a few degrees in the same period. The temperature displayed by a thermometer dipped into the crankcase oil is not therefore a determining factor.

In addition to the shaft speed, which is the most important factor, other parameters influence the heating of the lip, such as the condition of the shaft surface, the tightness of the seal, the ventilation of the crankcase, and so on, so that it is very difficult to know the temperature of the lip in continuous operation.

The temperatures indicated in the table below are only valid if the fluid being sealed is not degraded at these temperatures.

Where high temperatures exceed the values shown in the table below, use seals in fluorinated elastomer.

Our technical services are at your disposal to reply to your questions about the properties of various mixes.

(1) Temperature at which the seal continues to function.

(2) Average operating temperature.

(3) Maximum permissible temperature for not more than 10 hours over the life of the seal.

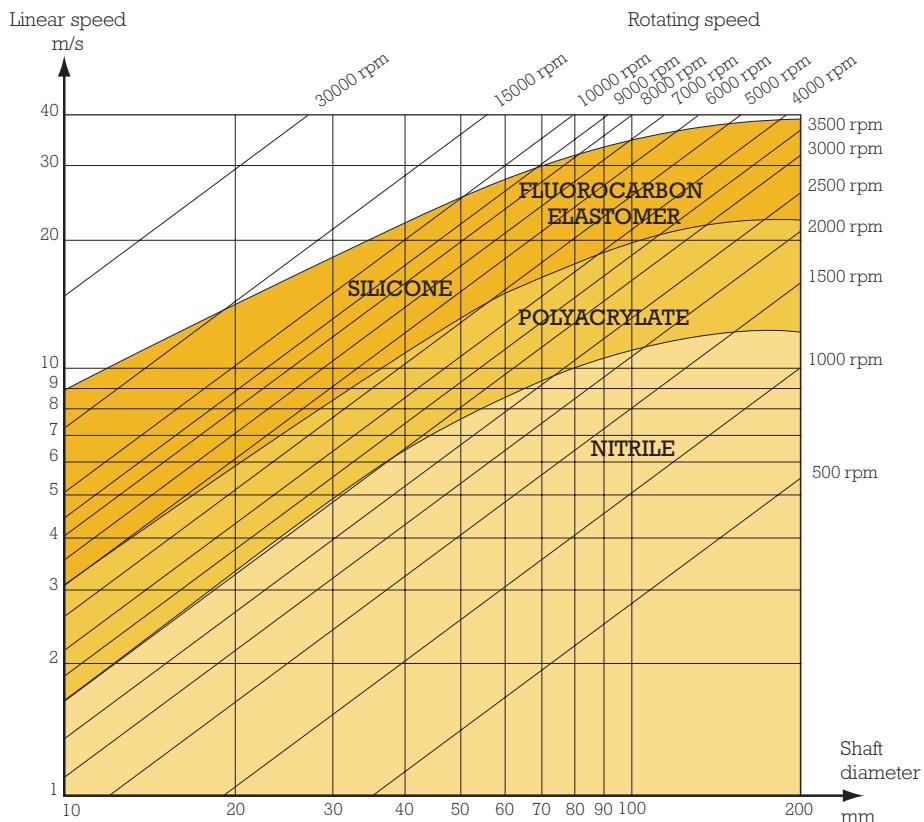

+ Resistant, but normally not used.

- Resistant, under certain conditions.

-- Does not resist.

IV.2 - SHAFT SPEED

The graph below gives an indication of the rotary or linear velocity of the shaft in relation to various elastomers which are permissible under normal conditions of use.

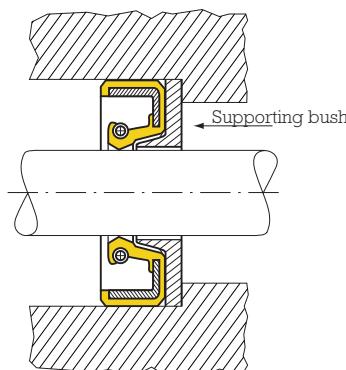

IV.3 - PRESSURE

The effective pressure to which a seal is submitted is the difference between the pressures of the fluids on each of its two sides (one of which is often the atmosphere). It is clear that the sealing lip should be found on the side which has the higher pressure. In theory, the lip seal for rotary shafts is not a pressure seal.

However, most PAULSTRA seals will resist pressures of the order of 0.5 bars without special precautions, if the velocities do not exceed 3 m/s. At higher pressures, there is a risk that the lip may be turned back on itself or pressed onto the shaft with a force which gives rise to an unacceptable tightness and frictional torque. At low velocities most PAULSTRA seals will bear pressures of up to 3 or 4 bars with the addition of a supporting bush. This is not provided by PAULSTRA, but it can be made up by the customer according to PAULSTRA's drawings.

The effective pressure is not necessarily constant. If the variations are slow and remain within the limits above, this is not a big problem. On the other hand, if they pulsate rapidly they can interfere with the performance of the seal.

You are advised to consult our Technical Services for any application which involves an effective pressure greater than 0.5 bars or a pulsating pressure.

V - CONDITIONS FOR GOOD OPERATION

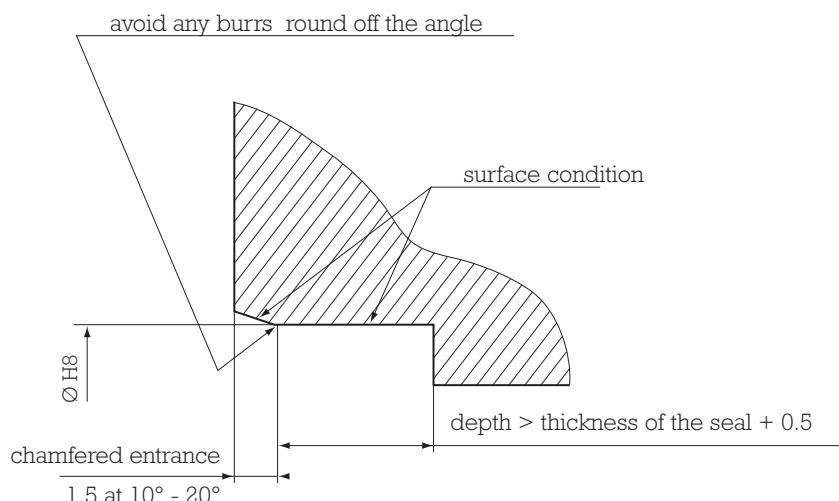

V.1 - THE HOUSING

It is extremely important that there be no sharp edges.

Our recommendations are shown on the figure below:

recommended shape of the housing:

- for a covered seal: $R = 4 \text{ to } 12.5 \mu$
 $Ra = 1.6 \text{ to } 4 \mu$
- for an external outer ring: $R = 3 \text{ to } 8 \mu$
 $Ra = 1.2 \text{ to } 2.5 \mu$

Note: if the housing is made of a material with a high coefficient of expansion. this must be taken into consideration when defining the interference (tightness) with the seal.

The lack of a chamfer. or too small a chamfer can cause:

- A deterioration of the exterior of the seals (cutting of the elastomer or stripping of the sealing lacquer).
- A big increase in the force of insertion. which could cause deformation of the outer ring.
- A defective axial positioning.

A surface with a very rough finish can cause the same problems and can therefore also be the reason for a leak. On the other hand. if the finish is too smooth the extraction force may be too low.

V.2 - THE SHAFT

The PAULSTRA recommendations are as follows :

- **Tolerance on the diameter** : h 11.
- **Surface state** : $R = 0.4$ to 1.2 ED (so $R_a \approx 0.2$ to 0.5).
- **Hardness** : if $V \leq 4$ m/s : 45 HRC minimum (say 455 HV or 155 kg/mm²), if $V > 4$ m/s : 55 HRC minimum (say 625 HV or 195 kg/mm²).
- **Thickness of the treated zone** : 0.3 mm minimum.
- **Circularity** : 5 microns.
- **Neutrality** : All machined surfaces have grooves from the machining process. If these grooves are inclined in relation to the axis of the shaft, they form a helix which will produce a hydrodynamic action.

The bearing surfaces of a seal must be neutral (i.e. there must be no orientation of the machining grooves).

It is possible to orient the machine grooves deliberately to produce pumping from the exterior to the interior of the mechanism. However, **we advise against this as there will be increased wear of the seal**.

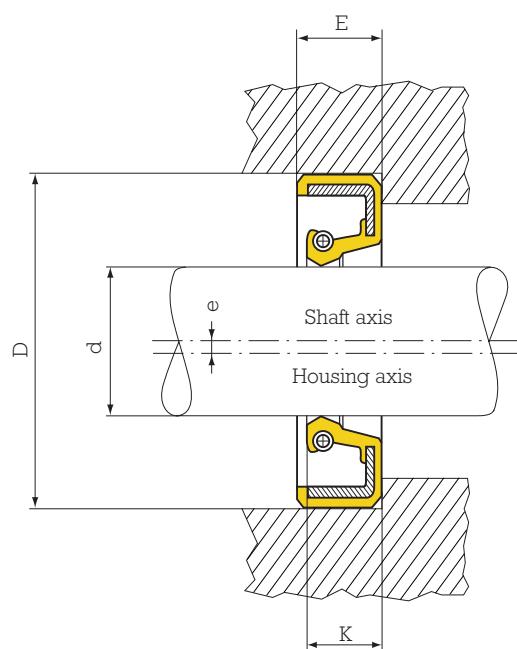

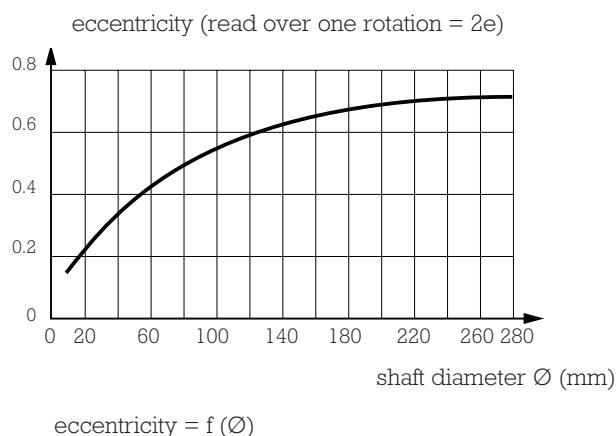

Hard chroming is also not to be recommended, unless it is of sufficient thickness and quality.

V.3 - ECCENTRICITY BETWEEN THE HOUSING AND THE SHAFT

The housing and the shaft should be centred on one another as precisely as possible. If there is a radial displacement between the axis of the seal and the axis of the shaft, the suppleness of the rubber lip enables assembly without "yawning" within certain limits.

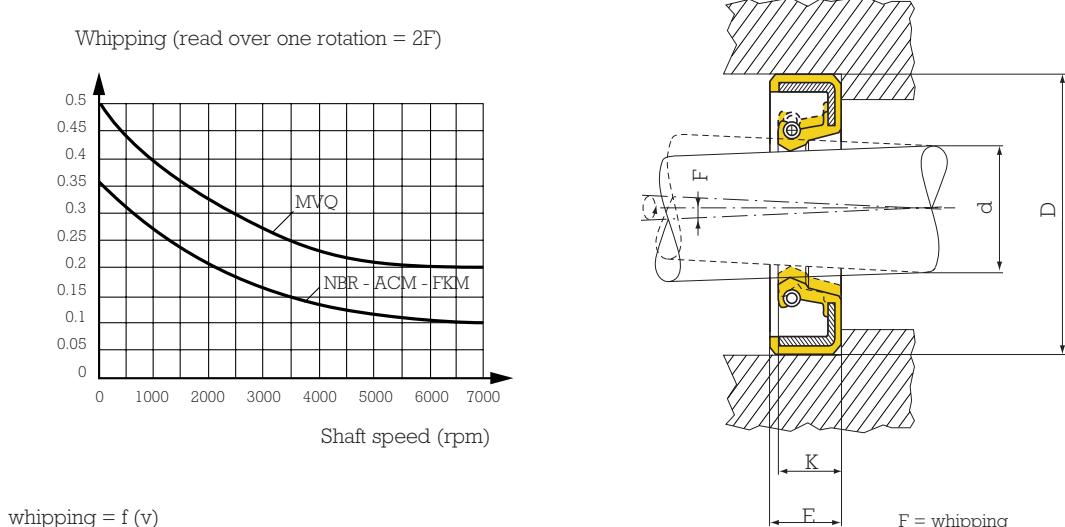

The eccentricity is the distance between the axis of the seal housing and the axis of the shaft, the two axes being parallel to each other.

The curve below shows the maximum permitted eccentricities as a function of the shaft diameter.

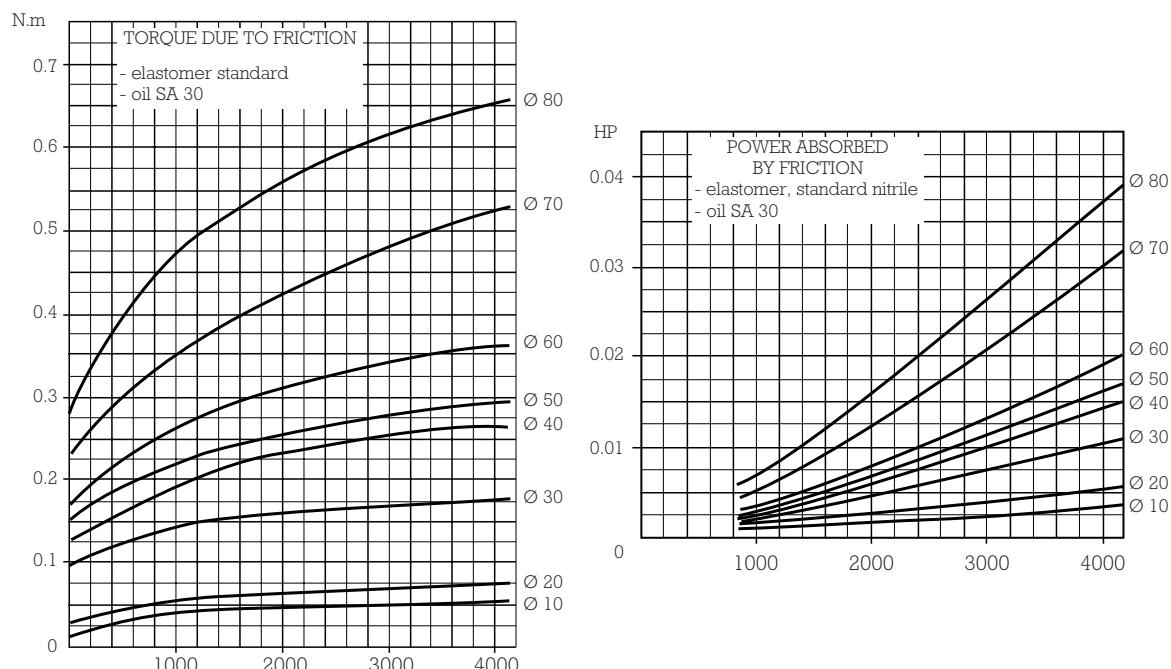

V.4 - WHIPPING OR OUT OF TRUE

This phenomenon occurs when the geometric axis of the shaft does not coincide exactly with the rotational axis. This can be the result, for example, of a worn bearing or the bending of the shaft. The amplitude of whipping increases with distance from a bearing, so the seal should be placed as near as possible to the bearings. Whipping is measured in mm, by the radius of the circle described by a point on the axis of the shaft which is in the same plane as the lip. The curve below shows the maximum whipping permissible as a function of the rotational velocity of the shaft.

V.5 - ABSORBED POWER - TORQUE DUE TO FRICTION

Due to its design, a lip seal produces friction which will provide some resistance to the rotation of the shaft. For a chosen speed, the resisting torque is function of : the shape of the seal, the friction coefficient and other environment factors such as (materials, tightness of the seal on the shaft, roughness of the shaft, wear, lubrication, temperature ...).

The curves above gives a first indication for the standard Nitrile elastomer. They were plotted under average working conditions using a standard seal with little wear and a lubricated shaft with good surface finish and running temperature of less than 100°C.

VI - THE ASSEMBLY OF SEALS

The assembly of seals is a very delicate operation which can ruin the efficiency of a very good product if it is not done properly.

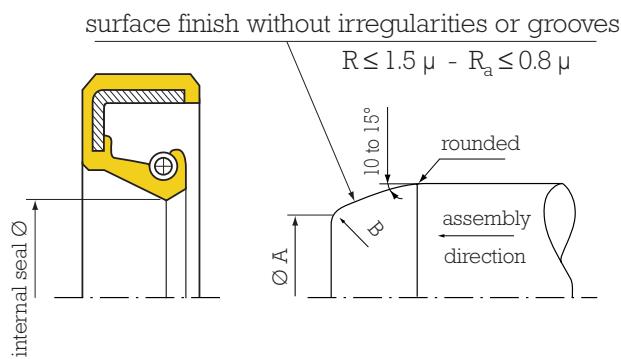

The assembly of a seal must be done in accordance with the following rules:

- Avoid damage to the lip.
- Avoid damage to the cover of the external diameter.
- Lubricate the sealing ridge to avoid damage at the first start-up.
- Position the seal correctly:
 - misalignment (the seal must be perpendicular in relation to the axis).
 - axial position.

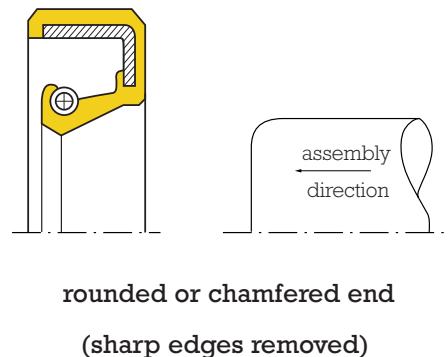

The information given below should help constructors to put these rules into practice.

VI.1 - ASSEMBLY ON A SHAFT WITHOUT SPLINES

fitting against the lip

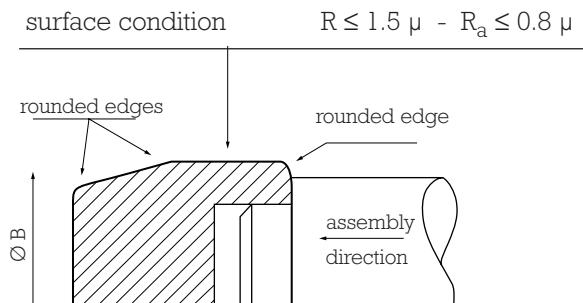

fitting with the lip

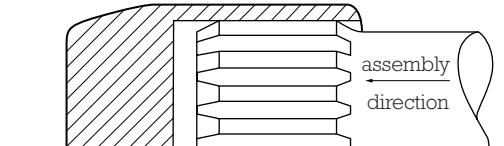

VI.2 - ASSEMBLY ON A SHAFT WITH SPLINES OR A SHOULDER

assembly tool for shouldered shaft

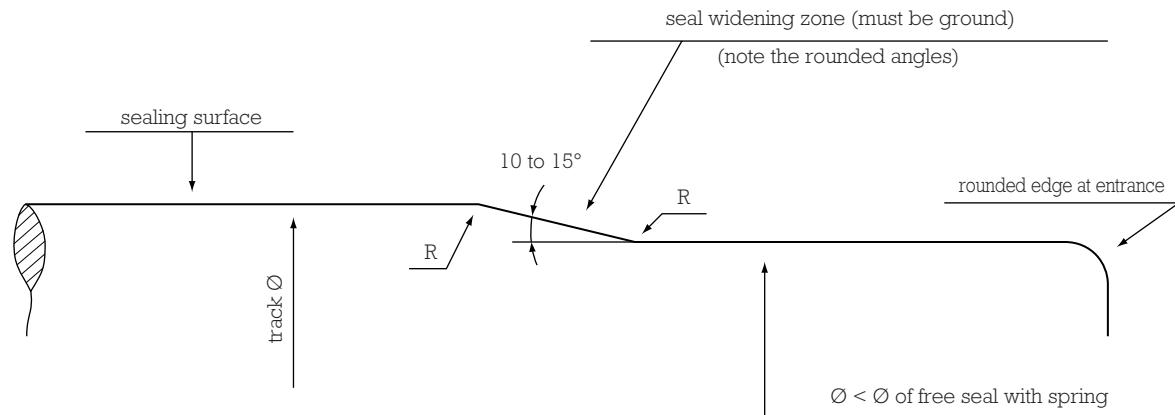

assembly tool for splined shaft

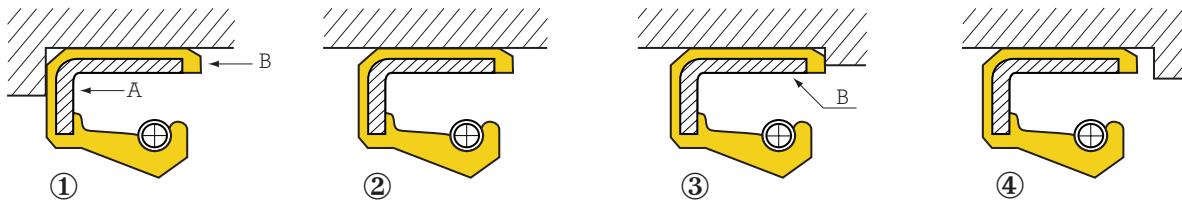

The use of these assembly tools is helpful. However, we recommend the use of a lead-in on the shaft whenever possible.

VI.3 - OUR RECOMMENDATIONS FOR THE SHAPE OF THE SHAFT

mounting sleeves are unnecessary, as the shaft has a lead-in

VI.4 - AXIAL POSITIONING AND ALIGNMENT

① The seal is mounted against a stop on the rear side. This presents no particular problem, provided that pressure is applied at "A" to insert it and not at "B".

② Here there is no axial stop. The mounting tool positions the seal both axially and perpendicularly.

③ The seal is mounted against a stop on the front side. This should be avoided as the elastomer at B could be compressed and the seal will tend to move out of position.

④ the housing has a shoulder as in ③, but the seal is positioned by the mounting tool. This case is preferable to case ③.

The mounting tool should be designed to position the seal correctly both axially and perpendicularly, but its shape should be such as to allow deformation of the elastomer covering the outer ring towards the rear, thus avoiding cutting the covering at the time of insertion. In some cases, the bead "C" does not get cut off and sticks between the housing and the assembly mandrel, in which case it is impossible to locate the seal, when the seals have an anti-dust lip, care should be taken that the mounting tools do not turn it back on itself.

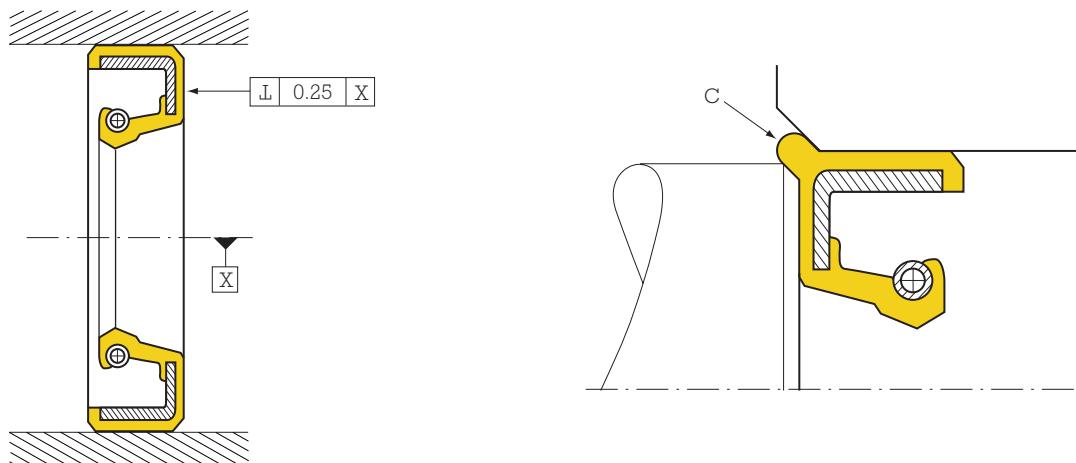

While it is true that modern seal design (corrugations on the outside, pre-centred shape, chamfers without burrs, etc.) tends to reduce problems during assembly, the comments made are still worth noting.

Also, the elastomer part of a semi-covered seal behaves in the same way as a fully covered seal.

- Time should be allowed during assembly to allow in order to allow the elastomer time to settle.
- The seal must be held in position for a few seconds once mounted, to avoid too large a return movement.

We recommend the following :

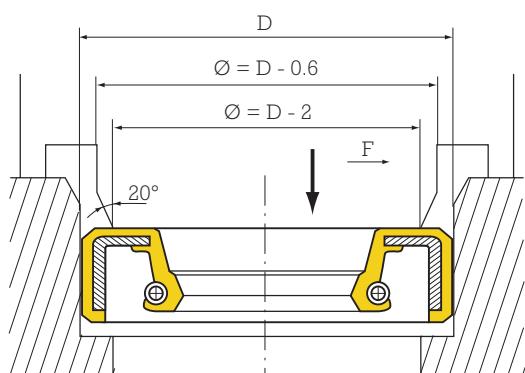

- $V = 1200 \text{ mm/mn}$ (maximum : 1500 mm/mn),
- time held in position: 5 seconds (minimum 2 seconds).

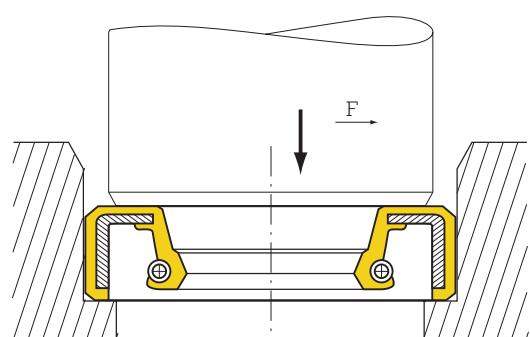

Formation of the bead

Perpendicular tolerance

VI.5 - RECOMMENDATIONS FOR THE ASSEMBLY TOOL

GOOD

TO BE AVOIDED

VI.6 - LUBRICATION AT ASSEMBLY

While the first means of avoiding damage to the outside of the seal is **to pay attention to the housing characteristics**, the second means, which is just as important, is **lubrication** :

- be it of the housing,
- or the outside of the seals,
- or both at the same time.

This not only avoids damage to the seal, but also ensures a better axial positioning.

A seal whose outside diameter is not lubricated will certainly be damaged on the outside when it is mounted in a dry housing (elastomer cover cut or ripped, sealing lacquer removed).

Also, when the unit is started up, the oil will always take some time before it reaches the lip of the seal (from a few seconds to a few tenths of seconds depending on the application).

If it is the first start, and if the lip has not been lubricated at assembly, it will function "dry" dynamically, which will lead to great wear and the risk of total deterioration.

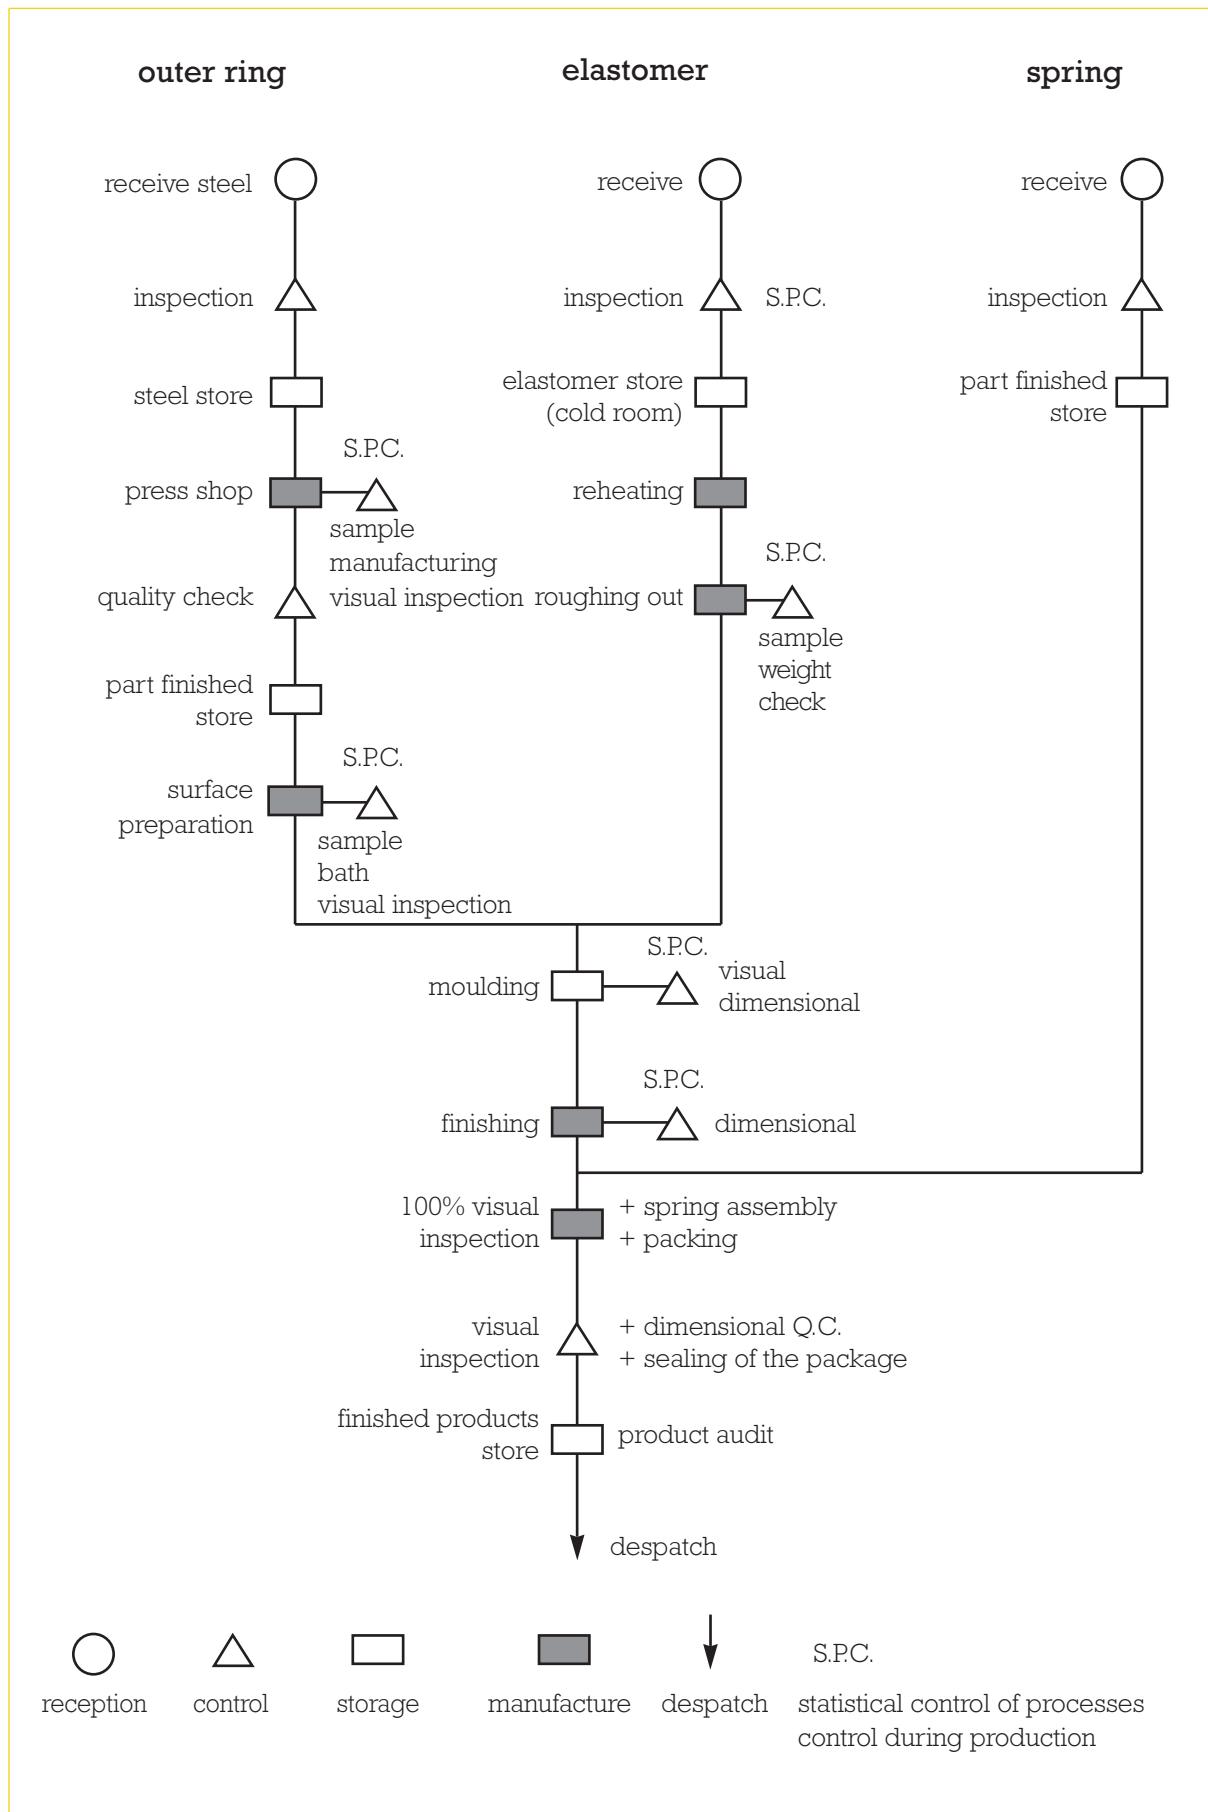

It is therefore essential to lubricate the sealing ridge.

For later starts, the problem is different, because a film of oil will be retained under the lip by capillarity action.

VI.7 - REMINDER OF THE MAIN PRINCIPLES OF ASSEMBLY

- Protect the lip and the outside of the seal by paying attention to the recommendations for the shaft and the housing.
- Apply the insertion force to the rigid part of the outer ring.
- Centre the seal correctly in relation to the housing and/or the shaft.
- Lubricate the outside diameter and/or the housing.
- Lubricate the sealing ridge.

VII - MANUFACTURE AND TESTING

VIII - CLASSIFICATION OF THE MAIN PROFILES OF LIP SEALS

	SPRING			CORRU-GATED COVER (W)	ANTI-DUST LIP		RIDGES		
	embedded (I)	visible (E)	none (O)		WITHOUT SPRING (L)	WITH SPRING (R)	to the left (G)	to the right (D)	bi-direct. (V)
I Covered outer ring	II 	IE 	IO 	IEW 	IEL 	IELR 	IEG 	IED 	IEV
E Bare outer ring	-	EE 	EO 	-	EEL 	EELR 	EEG 	EED 	EEV
CS Bare outer ring reinforced	-	-	-	-	CSEL 	-	-	-	-
M Semi-covered outer ring	-	ME 	MO 	MEW 	MEWL 	MEWLR 	MEG 	MED 	MEV

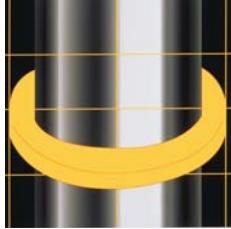

Note : other cases are available

X = exterior lip
S = special cross-section
P = protector

New range :
CSEL
seals with bare outer ring reinforced

CLASSIFICATION EXAMPLE

M Semi-covered	M Semi-covered	M Semi-covered
E Spring visible	E Spring visible	O No spring
W With corrugations	W With corrugations	W With corrugations
L R Anti-dust lip with spring	G Ridges to the left	L Anti-dust lip

CSEL Seals

SEALS WITH NITRILE AND FLUOROCARBON ELASTOMER

Due to low demand we have now stopped making the II/IIL range of seals (with moulded in spring). Please refer to our cost effective standard range of seals (IE/IEL or CSEL type in both Nitrile or Fluorocarbon elastomer) to find the nearest equivalent. Our Technical support service is at your disposal to help you.

The fluorocarbon seals previously with the suffix 83 now have the suffix 81. Suffix 83 parts may be delivered until stocks are replaced with parts having the suffix 81.

The part numbers indicated in bold type are kept in stock.

**Stainless steel spring.

Abbreviations: NBR = Nitrile; FKM = Fluorocarbon; SIL = Silicone; POL = Polyacrylate;

EPD = EPDM; S (in "Type" column) = special shape.

The fluorocarbon seals previously with the suffix 83 now have the suffix 81. Suffix 83 parts may be delivered until stocks are replaced with parts having the suffix 81.

The part numbers indicated in bold type are kept in stock.

Abbreviations: NBR = Nitrile; FKM = Fluorocarbon; SIL = Silicone; POL = Polyacrylate;

**Stainless steel spring.

EPD = EPDM; S (in "Type" column) = special shape.

The fluorocarbon seals previously with the suffix 83 now have the suffix 81. Suffix 83 parts may be delivered until stocks are replaced with parts having the suffix 81.

The part numbers indicated in bold type are kept in stock.
**Stainless steel spring.

Abbreviations: NBR = Nitrile; FKM = Fluorocarbon; SIL = Silicone; POL = Polyacrylate; EPD = EPDM; S (in "Type" column) = special shape.

SEALS FOR SLIDING SHAFTS

DIMENSIONS

● Width of the groove: E + 1 mm (for DL).

● Operating parameters:

Maximum admissible pressure: 150 bars (for DL) ; 30 bars (for LIO, LEO).

Linear speed admissible: up to 0.3 m/sec depending on the operating conditions.
